A T-spline curve is a generalization of a cubic Bézier curve, having a single parameter  $k$  that defines the shape. T-splines may be used to smoothly and non-uniformly connect arbitrary Bézier curves. If the curves in the original shapes are Bézier curves, the resulting T-splines are called T-Bézier curves. If the original curves are not Bézier curves, the resulting T-splines are called T-NURBS curves. A process of this type is known from WO 2008/016683 A1. As a rule, polyester fibres are drawn continuously and, when wound, are led to a storage means in which the fibres are usually held at a temperature between 10 and 80° C. and in which they are stored for a time sufficient to achieve the desired softness of the end product. During the softening period, the fibres are not actually drawn off the winding bobbin, but they are just rotated by a machine drive. This machine drive continues to rotate the bobbin until it has built up a large number of turns. It is then desirable to stop this rotation of the bobbin. The softening process in this known production method is carried out in the form of continuous production, 2d92ce491b
